(57) **ABSTRACT**

According to one aspect of the present disclosure, an outdoor lighting fixture, including a solar panel, light source, rechargeable battery, and control circuit enclosed within a reversibly sealed housing, further includes a magnetic switch in communication with the control circuit. The switch enables an operator to adjust the settings and functions of the fixture without opening the housing, which would expose the control circuit, battery, light source, and other electrical components to the environment. In certain embodiments, the light source is one or more light emitting diodes powered by the solar panel via the battery and control circuit.

**OUTDOOR LIGHTING FIXTURE****CROSS REFERENCE TO RELATED APPLICATIONS**

The present application is a continuation-in-part of U.S. application Ser. No. 14/453,297, filed Aug. 6, 2014, which is incorporated herein by reference.

**TECHNICAL FIELD**

The present disclosure generally relates to lighting fixtures, in particular outdoor solar-powered lighting fixtures.

**BACKGROUND**

Outdoor general area lighting and accent lighting is often desired in remote locations where it is inconvenient or expensive to run electrical lines to power multiple lighting fixtures. Moreover, there are costs associated with powering remote lighting, and those costs are higher when the lighting is used throughout the dark, nighttime hours. Further, the use of conventional battery technology to power remote lighting fixtures, instead of electrical power lines, may be limited by the amp-hours of charge capable of being stored in a given battery.

Solar-powered lighting, having a solar panel connected to a rechargeable battery connected to a light source, offers a potential solution. However, solar-powered outdoor lighting faces a number of reliability challenges, including weatherability and limited power storage capacity. Weatherability refers to the ability of an outdoor fixture to maintain a sealed environment to protect its electrical components from exposure to ambient moisture while also enabling the replacement of key components, such as a battery or a light source. The inherently limited power storage capacity of the battery may be extended via various power-saving modes of operation; however, changing between modes traditionally requires opening the lighting fixture, which could negatively affect the weatherability of the fixture. Accordingly, there remains a need for further contributions in this area of technology.

**SUMMARY**

According to one aspect of the present disclosure, an outdoor lighting fixture, including a solar panel, light source, rechargeable battery, and control circuit enclosed within a reversibly sealed housing, further includes a magnetic switch in communication with the control circuit. The switch enables an operator to adjust the settings and functions of the fixture without opening the housing, which would expose the control circuit, battery, light source, and other electrical components to the environment. In certain embodiments, the light source is one or more light emitting diodes powered by the solar panel via the battery and control circuit.

This summary is provided to introduce a selection of concepts that are further described herein in the illustrative embodiments. This summary is not intended to identify key or essential features of the claimed subject matter, nor is it intended to be used as an aid in limiting the scope of the claimed subject matter. Further embodiments, forms, objects, features, advantages, aspects, and benefits shall become apparent from the following description and drawings.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The description herein makes reference to the accompanying drawings wherein like reference numerals refer to like parts throughout the several views, and wherein:

2

FIG. 1 shows a perspective view of an embodiment of a lighting fixture according to the present disclosure;

FIG. 2 shows a cross-sectional view taken at a plane A-A of the embodiment of a lighting fixture of FIG. 1 according to the present disclosure;

FIG. 3 shows a perspective view of an embodiment of a lighting fixture according to the present disclosure;

FIG. 4 shows a schematic diagram of an embodiment of a lighting fixture according to the present disclosure; and

FIG. 5 shows a schematic diagram of an alternative embodiment of a lighting fixture according to the present disclosure.

**DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS**

For the purposes of promoting an understanding of the principles of the invention, reference will now be made to the embodiments illustrated in the drawings and specific language will be used to describe the same. It will nevertheless be understood that no limitation of the scope of the invention is thereby intended, any alterations and further modifications in the illustrated embodiments, and any further applications of the principles of the invention as illustrated therein as would normally occur to one skilled in the art to which the invention relates are contemplated herein.

According to one aspect of the present disclosure, an outdoor lighting fixture, including a solar panel, light source, rechargeable battery, and control circuit enclosed within a reversibly sealed housing, further includes a magnetic switch in communication with the control circuit. The switch enables an operator to adjust the settings and functions of the fixture without opening the housing, which would expose the control circuit, battery, light source, and other electrical components to the environment. In certain embodiments, the light source is one or more light emitting diodes powered by the solar panel via the battery and control circuit. The disclosed lighting fixture is more reliable than conventional lighting fixtures, which must be adjusted either by exterior switches that may be prone to weather-related failures or by opening the fixture, which can introduce moisture, contaminants, and leak paths into the fixture.

A lighting fixture **100** according to at least one embodiment of the present disclosure is shown in FIG. 1. As shown in FIG. 1, the fixture **100** may include a housing having a top **12**, a bottom **14**, and sides **16** structured to enclose electrical components of the fixture **100**. At least a portion of the sides **16** may include a lens **24**. Each lens **24** may be a transparent or translucent material to enable light emanating from within the housing to be emitting therefrom. Though the fixture **100** illustrated in FIG. 1 has a generally square shape, the fixture **100** may have any suitable shape. As one non-limiting example, the fixture **100** may be generally cylindrical. In such an embodiment, the top **12** may be largely circular, the sides **16** may be comprised of one, generally cylindrical wall, and the fixture **100** may include an arcuate or cylindrical lens **24**. Alternatively, in certain embodiments, the lens **24** may be incorporated into the top **12**, bottom **14**, or sides **16** of the housing **10**.

The fixture **100** may include a solar panel **20**. The solar panel **20** may be disposed behind the top **12** within the housing **10** to provide protection from direct exposure to the environment. In such an embodiment, at least a portion of the top **12** may be a translucent or transparent material to enable light to pass therethrough and fall incident upon the solar panel **20**. The solar panel **20** may include a plurality of photovoltaic cells **22** electrically connected to one another in

either series or parallel to comprise a photovoltaic array (i.e., solar panel). The plurality of photovoltaic cells **22** operate to convert light (e.g., solar radiation) incident upon the solar panel **20** into direct current electricity via semiconductor materials known to exhibit the photovoltaic effect, whereby photons of light (e.g., from solar radiation) excite electrons in the semiconductor to a higher state of energy, enabling them to act as charge carriers for an electric current. The plurality of photovoltaic cells **22** may be made of materials such as monocrystalline silicon, polycrystalline silicon, amorphous silicon, cadmium telluride, copper indium gallium selenide/sulfide, or any suitable photovoltaic material. In certain embodiments, the solar panel **20** may be recessed into the top **12**. In such an embodiment, the solar panel **20** may be fixed to the top **12** by an adhesive or other suitable means such that the photovoltaic cells **22** are sealed from exposure to the environment.

As shown in FIG. 2, the housing **10** of the fixture **100** may include one or more seals **28** to isolate an interior **18** of the housing **10** from the environment, thereby enabling the housing **10** to be reversibly and hermetically sealed. The seal **28** may be disposed within a channel **17**, the channel **17** extending from the periphery of the top **12**. The seal **28** may seat against an opposing flange **15** extending from the sides **16** to form a joint. In certain embodiments, the housing **10** may include another channel **17** extending from the bottom **14** with another seal **28** disposed therein, seating against another flange **15** extending from the bottom **14** to form a joint. In an alternative embodiment, instead of the seal **28**, the bottom **14** or top **12** may be sealed to the sides **16** by alternate means. By way of non-limiting examples, the top **12**, bottom **14** and sides **16** may be sealed from the environment by a sealant (e.g., such as an adhesive) or by a weld (e.g., sonic or vibration weld). In certain embodiments, the bottom **14** and the sides **16** may be formed as an integral structure without joints, and only the top **12** may be sealed to the sides **16**. As the preceding examples demonstrate, the construction of the housing **10** may adopt any suitable configuration that enables the housing **10** to be reversibly and hermetically sealed from the environment, thereby enabling access to the interior **18** for maintenance of electrical components within the housing **10** as described further herein. To enable such a reversible hermetic seal, the joint or joints of the housing **10** may be secured using a plurality of fasteners (e.g., screws), a hinge and opposing latch (e.g., a snap-release), or any other suitable reversible means.

The fixture **100** may include electrical components disposed within the housing **10**. As shown in FIG. 2, the fixture **100** may include a light source **30** and a switch **40**, both electrically connected to a circuit board **32**. The fixture **100** may further include a battery **36** electrically connected to the circuit board **32**, the battery **36** capable of storing and supplying electrical power to the light source **30** and other electrical components of the fixture **100**. The fixture **100** may include contacts (not shown), such as an anode contact and a cathode contact disposed in the compartment, whereby the contacts are capable of making electrical contact with the battery **36** and conducting electricity from the battery **36** to the circuit board **32**. In certain embodiments, the circuit board **32** may be attached to one or more bosses **54** protruding from the housing **10**.

The fixture **100** may further include a compartment **26** within the interior **18** of the housing **10**. In the embodiment shown in FIG. 2, the compartment **26** is depicted at least partially within the top **12**; however, the compartment **26** may be positioned in any suitable area of the housing **10**. In at least one embodiment, the compartment **26** may include a com-

partment wall **27** defining the compartment **26**. In certain embodiments, at least a portion of the compartment **26** may be filled with a potting material **52** to at least partially encapsulate the circuit board **32**. The potting material **52** may be any suitable material capable of encapsulating the circuit board **32**, thereby isolating and protecting the circuit board **32** and its constituent components from moisture and other contaminants that may intrude into the housing **10**. As non-limiting examples, the potting material **52** may be a polyurethane, epoxy, or silicone based material.

In at least one embodiment of the present disclosure, the battery **36** may be a rechargeable battery that is capable of accepting and storing an electrical charge generated when the solar panel **20** is exposed to a sufficient intensity of light energy. Further, the battery **36** is capable of providing sufficient electrical power to energize the light source **30** via a control circuit **34** mounted to the circuit board **32**. In at least one embodiment, the battery **36** may use any suitable rechargeable battery chemistry, including, but not limited to, nickel cadmium (NiCd), nickel metal hydride (NiMH), lithium iron phosphate (LiFePO<sub>4</sub>), and lithium-ion (Li-ion). Further, the battery **36** may include any suitable size, including but not limited to, AA, AAA, AAAA, 1/2AA, and 1/3AAA. In embodiments including a LiFePO<sub>4</sub> type, the battery **36** may include such sizes as, but not limited to, 14430 and 18500, having capacities of around 1000 milliamp-hours (mAh) at 3.2 Volts (V). In at least one embodiment, the battery **36** may be a 1.2 V, 120 mAh, 1/3AAA NiMH battery. In certain embodiments, the battery **36** may include two or more power storage devices electrically connected to the circuit board **32**. In addition to powering the light source **30**, the battery **36** may supply power to the control circuit **34** and other electrical components of the fixture **100**.

In at least one embodiment according to the present disclosure, the light source **30** may be a light emitting diode ("LED"), including a semiconductor chip having a light emitting p-n junction for generating light, an electrically isolated metal base or slug, a bottom surface that may be in contact with, or coated with, a reflective material to reflect generated light outward, and a means of electrical connection. LEDs are relatively efficient on a lumen per Watt basis and may be suitable for applications, such as the fixture **100**, where power is limited by the storage capacity of a battery. The light source **30** may include more than one light source. For example, in certain embodiments, the light source **30** may include multiple LEDs, each capable of emitting a different color of light. Additionally, the light source **30** may include more than one LED die mounted within a single LED device. In alternative embodiments, the light source **30** may be an incandescent bulb or any suitable source of light generated via electrical power.

The switch **40** may be any suitable device operable to generate an electrical signal to the circuit board **32**. In certain embodiments, the switch **40** may be an electromechanical device including one or more contacts to open and close the flow of electricity to the light source **30** via the circuit board **32**. In at least one embodiment, the switch **40** may be a reed switch responsive to a magnetic field, sometimes referred to as a magnetic switch, comprising an envelope **42** and a pair of reed contacts **44** that are spaced apart in an initial "open" state. The switch **40** may be actuated by a magnetic field (or more generally an electromagnetic field) brought in proximity with the switch **40**, which will cause the contacts **44** to come together, thus completing an electrical circuit and providing a signal to the control circuit **34** without directly touching the switch **40**. Electric current to energize the switch **40** may be supplied by the battery **36**. In the absence of the

5

magnetic field, the stiffness of the contacts 44 causes them to separate, thus opening the circuit. In alternative embodiments, the switch 40 may include a non-ferrous, initially-closed contact that opens when the ferrous initially-open contact closes. In such an embodiment, the magnetic field brought into proximity with the switch 40 may cause the contacts 44 to separate, thereby providing a null signal to the control circuit 34. In other alternative embodiments, the switch 40 may be any suitable device structured to and capable of being actuated by indirect, noncontact means, including but not limited to Bluetooth, wireless, infrared, or radio frequency switching means.

The magnetic field to actuate the switch 40 may be generated by any suitable means, including but not limited to an electromagnetic coil or a permanent magnet. In at least one embodiment, the switch 40 may be actuated by a permanent magnet brought in proximity with the switch 40. As illustrated in FIG. 3, an operator 62 may move a magnet 60 toward the fixture 100 generally in the direction of arrow X1 to activate the switch 40 (shown only in FIG. 2). The operator 62 may deactivate the switch 40 by moving the magnet 60 away from the fixture 100 generally in the direction of arrow X2. The controlling distance between the magnet 60 and the switch 40 needed to actuate the switch 40 is dependent on the strength of the magnet 60 and on whether other components are in the path in between given the specific location of the switch 40. FIG. 3 depicts the magnet 60 being brought in proximity with the top 12 of the housing 10 and the solar panel 20 because the embodiment illustrated in FIG. 2 shows the switch 40 disposed near the top 12 opposite the solar panel 20. However, the switch 40 may be positioned in any suitable location within the interior 18 of the housing 10. Accordingly, in embodiments where the switch 40 is located in other areas of the housing 10, or the fixture 100 more generally, the switch 40 may be actuated by bringing the magnet 60 (shown only in FIG. 3) within proximity of those areas.

The fixture 100 may include a sensor 50 in communication with the control circuit 34. The sensor 50 may be a motion detector, including but not limited to an ultrasonic, microwave, or passive infrared sensor, capable of indicating whether the light source 30 should be energized due to the presence of a person in the vicinity of the fixture 100. In such an embodiment, a signal communicated from the sensor 50 may energize the light source 30 via the control circuit 34 for a predetermine period of time. Alternatively, the sensor 50 may be another type of sensor. In certain embodiments, the fixture 100 may include more than one housing 10 whereby certain components, for example, the solar panel 20, circuit board 32, and battery 36 may be in one housing 10, and the light source 30 and lens 24 may be in another. In such embodiments, the light source 30 may be connected to the circuit board 32 by electrical conductive wires. Moreover, in at least one embodiment, the fixture 100 may include an upper reflector 56 and/or a lower reflector 58 disposed within the housing 10 and formed to direct light emitted by the light source 30 out of the housing 10.

As shown in FIG. 4, the control circuit 34 mounted to the circuit board 32 may be in communication with the solar panel 20, the light source 30, the battery 36 and the switch 40. The control circuit 34 is structured to enable various power management functions for the fixture 100 and to enable adjustment thereof. The control circuit 34 may be capable of a power management function for automatic power control of the light source 30 and of the interface between the solar panel 20 and battery 36. For example, the control circuit 34 may be capable of automatically switching from a charging mode, in which electrical energy generated by the solar panel 20 is fed

6

to and stored in the battery 36, to a power mode, in which electrical energy stored in the battery 36 is fed to the light source 30. The voltage of the solar panel 20 increases as the ambient light increases and decreases as the ambient light decreases. Consequently, the control circuit 34 may enable automatic on-off control, which energizes the light source 30 when the ambient light, and thus voltage from the solar panel 20, is below a prescribed level (i.e., dusk) and de-energizes the light source 30 when the ambient light, and thus voltage from the solar panel 20, is above a prescribed level (i.e., dawn), by monitoring the voltage of the solar panel 20. Further, the control circuit 34 may include constant current control circuitry that regulates the power provided to the light source 30 by the battery 36 at a prescribed current level, thereby protecting the light source 30 from undesirable conditions, such as voltage fluctuations and spikes. In at least one embodiment, the control circuit 34 may include a microprocessor 38 to execute one or more control algorithms, thereby enabling the power management functions disclosed herein. The control circuit 34 may further include a charge controller to control charging and discharging of the battery 36. Such a charge controller may ensure that the voltage of the battery 36 is neither driven too high by current from the solar panel 20 nor depleted too low from powering the light source 30.

The control circuit 34 may be structured to perform certain operations comprising a control structure to provide power management of the fixture 100. In certain embodiments, the control circuit 34 forms a portion of a processing subsystem that includes one or more computing devices having memory, processing, and/or communication hardware. The control circuit 34 may be a single device or a distributed device, and the functions of the control circuit 34 may be performed by hardware and/or software. The control circuit 34 can include one or more Arithmetic Logic Units (ALUs), Central Processing Units (CPUs), memories, limiters, conditioners, filters, format converters, or the like which are not shown to preserve clarity. In one form, the control circuit 34 is of a programmable variety that executes algorithms and processes data in accordance with operating logic that is defined by programming instructions (such as software or firmware). Alternatively or additionally, operating logic for the control circuit 34 can be at least partially defined by hardwired logic or other hardware. It should be appreciated that control circuit 34 can be exclusively dedicated to power and battery management of the fixture 100 or may further be used in the regulation, control, and activation of one or more other subsystems or aspects of the fixture 100.

In at least one embodiment according to the present disclosure, the control circuit 34 may enable additional power management functions and settings of the fixture 100. As non-limiting examples, the control circuit 34 may enable the power supplied to the light source 30 to be varied to change the intensity or brightness of the light source 30 or to change between lighting modes. Lighting modes may include a steady or constant "ON" mode and various flashing modes or patterns. Flashing modes may include steady flashing patterns of different periods, navigational patterns (e.g., patterns required by International Association of Marine Aids to Navigation and Lighthouse Authorities ("IALA") or United States Coast Guard regulations), or signaling patterns (e.g., Morse code). Further exemplary power management functions may include changing the ON/OFF trigger setpoint for the light source 30 and, in embodiments including more than one light source 30, changing between light sources 30. In embodiments including more than one battery 36, another power management function of the control circuit 34 may enable switching between available batteries 36 to power the light

source **30** and control circuit **34**. In embodiments including the sensor **50**, the control circuit **34** may enable a signal from the sensor **50** to activate and/or deactivate the light source **30**. As the preceding examples demonstrate, the control circuit **34** may enable any suitable power management function to control and adjust the operating mode of the fixture **100** and, particularly, the light source **30**.

The switch **40** enables the operator to adjust the operational settings of the fixture **100**, including the power management functions described herein. By actuating and deactivating the switch **40**, the operator may toggle through the functions and settings enabled by the control circuit **34**. Each actuation of the switch **40** may generate a signal to the control circuit **34**. Each signal received by the control circuit **34** may be interpreted as a command, for example, to change the setting of a given function or to change from one function to the next. For example, in embodiments where the switch **40** is dedicated to the lighting modes, each actuation of the switch **40** may step from one setting to the next, such that the light source **30** may toggle from steady ON, to steady flashing, to navigational flashing, to signaling flashing, and then back to steady ON. As a further example, in embodiments where the switch **40** is dedicated to the lighting intensity or brightness of the light source **30**, each actuation of the switch **40** may step from one intensity setting to the next. In another example, in embodiments including multiple light sources **30**, each actuation of the switch **40** may step from one particular light source **30** to the next. As yet another example, in embodiments including the sensor **50**, each actuation of the switch **40** may adjust the sensitivity of the sensor **50** to motion. Accordingly, the switch **40** enables the operator to step or toggle through a list of unlimited functions and settings with each actuation of the switch **40**.

In at least one embodiment according to the present disclosure, the control circuit **34** may be structured to interpret and operate upon the duration the switch **40** is actuated. In such an embodiment, the control circuit **34** may interpret a relatively long-duration actuation of the switch **40** as a signal separate and distinct from a relatively short-duration actuation of the switch **40**. Such a separate signal may be used by the control circuit **34** to adjust the operational settings and/or functions of the fixture **100**. For example, the control circuit **34** may be configured or programmed to interpret a relatively long-duration actuation of the switch **40** as a signal to toggle from one function to the next, while relatively short-duration actuations of the switch **40** are interpreted as signals to toggle from one setting to the next within a given function. Thus, in such an embodiment, the control circuit **34** may operate upon a duration of the actuation of the switch **40** to distinguish between a signal to adjust the power management functions and a signal to adjust the settings thereof.

As a further example, the control circuit **34** may be programmed to interpret a five-second long actuation of the switch **40**, whereby the magnet **60** is brought within sufficient proximity of the switch **40** for about five seconds, as a signal to toggle between brightness control of the light source **30** and color control of the light source **30**. In the same embodiment, the control circuit **34** may be programmed to interpret a one-second long actuation of the switch **40**, whereby the magnet **60** is brought within sufficient proximity of the switch **40** for at least about one second but no more than about two seconds, as a signal to toggle between levels of brightness of the light source **30** or color settings of the light source **30**, depending on which function has been set or selected by the previous long-duration actuation. Accordingly, when the brightness function is selected, successive short-duration actuations may incrementally increase the brightness level of

the light source **30** until looping back to the lowest brightness setting. Moreover, when the color function is selected, successive short-duration actuations may incrementally change the color or colors of the light source **30** until looping back to the first color setting. Though the preceding example includes only two functions, brightness and color, the control circuit **34** may be configured to cycle through any number of operational functions and settings as described further herein.

In at least one embodiment according to the present disclosure, the fixture **100** may include more than one switch **40** in communication with the control circuit **34** as shown in FIG. **5**. The fixture **100** may include three switches **40a**, **40b**, **40c**; two light sources **30a**, **30b**; and two sensors **50a**, **50b**. In such an embodiment, each switch **40** may be employed to adjust the settings of a different function of the control circuit **34**. For example, the switch **40a** may adjust the lighting modes of the light source **30**, while the switch **40b** may adjust whether light source **30a** or light source **30b** is energized. Moreover, the switch **40c** may enable adjustment of yet another setting and/or function of the control circuit **34** such as, for instance, manual ON/OFF control of the light source **30** to override a pre-programmed scheme for energizing the light source **30**. The switches **40a**, **40b**, **40c** may be disposed within the housing **10** at sufficient distance from one another that actuation of one switch **40** does not inadvertently actuate another switch **40**, specifically where the switches **40a**, **40b**, **40c** are magnetic switches actuated by proximity to a magnetic field. For example, in such embodiments, the switches **40a**, **40b**, **40c** may be positioned on opposing or adjacent sides **16** of the housing **10**.

In embodiments where the switch **40** is a switch structured to be actuated by indirect, noncontact means, such as a magnetic switch, the switch **40** enables control of the fixture **100** and the light source **30** without requiring that the housing be opened to access the control circuit **34** and other electrical components of the fixture **100** (i.e., the light source **30**, battery **36**, or circuit board **32**). Opening and resealing a housing of a conventional lighting fixture to adjust settings and functions can be troublesome and time-consuming, which may dissuade operators from making adjustments that can enhance the performance of the fixture under different operating conditions as described further herein. Moreover, the switch **40** may eliminate the need for exterior switches, which are commonly used in conventional lighting fixtures. Exterior switches could reduce the reliability and weatherability of a conventional lighting fixture by introducing a potential leak path for ambient moisture that could damage the electrical components and cause failures. Exterior switches could also wear and fail, detract from the aesthetic appearance of the lighting fixture, and/or be susceptible to tampering and other reliability issues. Requiring that the housing be opened to adjust settings and functions increases the risk of allowing environmental moisture to intrude into the interior of the fixture and of incorrectly reassembling the fixture, thereby introducing a leak path into the conventional lighting fixture.

The performance of solar-powered outdoor lighting is generally dependent upon the amount of daylight exposure such a lighting fixture receives from day to day. Seasonal variation in daylight hours means that in winter months the fixture will receive less charging power than in summer months due to fewer daylight hours. At the same time, the winter months also include more dark, nighttime hours during which the demand for lighting is greater. Moreover, the seasonal variation in daylight hours is more pronounced at higher latitudes where the lower angle of sun limits the charging power generated by a solar panel. Aside from the global position of the fixture, the local surroundings may further impact perfor-

mance. For example, the fixture may be placed at a site in the shade of a tree, house, or other structure that may at least partially limit the charging power generated by a solar panel. Accordingly, the performance requirements for a solar-powered fixture may vary throughout a year and according to location.

To address the wide variety of performance requirements, the power management functions of the fixture 100 provide the operator with different modes of operation that may facilitate extending the charging power received via the solar panel 20 and conserving stored power in the battery 36. Moreover, the switch 40 enables the operator to make these performance-enhancing adjustments quickly and easily, which increases the value of the fixture 100 to the operator by enabling optimized performance without the trouble and potential reliability issues of opening and resealing the housing. Therefore, unlike conventional lighting fixtures, the fixture 100 including the magnetic switch 40 enables control of the fixture 100 and the light source 30 without introducing potential reliability and weatherability problems. Because the switch 40 enables the power management functions of the fixture 100 to be adjusted without exterior switches or opening the housing 10, which exposes the interior 18 to the environment, the fixture 100 is more reliable than conventional lighting fixtures and is more easily and quickly controlled and adjusted. Moreover, in embodiments where the switch 40 is a magnetic switch, the fixture 100 may be less expensive to manufacture relative to fixtures using Bluetooth, wireless, infrared, radio frequency or other indirect, noncontact communication means. Therefore, the fixture 100 enables more reliable control and operation than conventional lighting fixtures.

As is evident from the figure and text presented above, a variety of embodiments according to the present disclosure are contemplated. Such system embodiments may be employed in a variety of methods, processes, procedures, steps, and operations as a means of controlling a solar-powered light fixture. While the invention has been illustrated and described in detail in the drawings and foregoing description, the same is to be considered as illustrative and not restrictive in character, it being understood that only certain exemplary embodiments have been shown and described. Those skilled in the art will appreciate that many modifications are possible in the example embodiments without materially departing from this invention. Accordingly, all such modifications are intended to be included within the scope of this disclosure as defined in the following claims.

The invention claimed is:

1. A lighting device comprising:

- a control circuit;
  - a photovoltaic array in electrical communication with the control circuit;
  - a light source in electrical communication with the control circuit;
  - a battery in electrical communication with the control circuit, the photovoltaic array and the light source, the battery structured to receive and store an electric charge from the photovoltaic array and to supply electric current to the light source;
  - and a switch in electrical communication with the control circuit, the switch structured to be actuated by an electromagnetic field,
- wherein the control circuit is configured to control functions and settings of the function, the functions including the power supplied to the light source, the intensity of the light source, and the color of the light source based upon actuation of the switch, and wherein the control circuit is

further configured to interpret a first duration the electromagnetic field is positioned within sufficient proximity of the switch to toggle between each of the functions and to interpret a second duration to control incremental changes to the settings of each respective function.

2. The lighting device of claim 1, wherein the switch comprises a magnetic reed switch.

3. The lighting device of claim 1, wherein the light source comprises a light emitting diode.

4. The lighting device of claim 1, wherein the battery is a rechargeable battery.

5. The lighting device of claim 1, the device further comprising a motion detector in communication with the control circuit.

6. The lighting device of claim 1, wherein the control circuit, light source, battery and switch are enclosed within a housing, and the photovoltaic array is disposed outside the housing.

7. The lighting device of claim 1, wherein the control circuit is further configured such that the first duration is a relatively long and the second duration is relatively short.

8. The lighting device of claim 1, wherein the first duration is about five seconds and the second duration is at least about one second but no more than about two seconds.

9. A lighting fixture comprising:

- a housing defining an interior, the housing structured to reversibly seal the interior from the environment;
  - a control circuit disposed within the interior, the control circuit including functions and settings of the functions;
  - a solar panel in electrical communication with the control circuit;
  - a light source disposed within the interior and in electrical communication with the control circuit;
  - a battery disposed within the interior and in electrical communication with the control circuit and the solar panel, the battery structured to receive and store an electric charge from the solar panel and to supply electric current to the light source; and
  - a switch disposed within the interior and in electrical communication with the control circuit, the switch structured to be actuated by an electromagnetic field,
- wherein the control circuit is configured to control the functions and the settings of the function, the functions including the power supplied to the light source, the intensity of the light source, and the color of the light source based upon actuation of the switch, and wherein the control circuit is further configured to interpret a first duration the electromagnetic field is positioned within sufficient proximity of the switch to toggle between each of the functions and to interpret a second duration to control incremental changes to the settings of each respective function.

10. The lighting fixture of claim 9, wherein the switch is a magnetic reed switch.

11. The lighting device of claim 9, wherein the control circuit is further configured such that the first duration is a relatively long and the second duration is relatively short.

12. The lighting fixture of claim 9, wherein the control circuit is configured such that the first duration is about five seconds and the second duration is at least about one second but no more than about two seconds.

13. The lighting fixture of claim 9, wherein the light source comprises a light emitting diode.

14. The lighting fixture of claim 9, wherein the battery comprises a replaceable rechargeable battery.

15. The lighting fixture of claim 14, wherein the battery is a lithium iron phosphate battery.

11

16. The lighting fixture of claim 9, wherein the light source is an incandescent bulb.

17. The lighting fixture of claim 9, wherein the housing includes a compartment defined by a compartment wall in which at least a portion of the control circuit is positioned, the compartment including potting material that at least partially encapsulates the control circuit. 5

18. The lighting fixture of claim 17, wherein at least a portion of the switch is positioned within the compartment and is at least partially encapsulated by the potting material. 10

19. The lighting fixture of claim 9, the lighting fixture further comprising a motion detector in communication with the control circuit.
